ACKNOWLEDGEMENTS

This report, published by the South African Network for Coastal and Oceanic Research (SANCOR), was supported and sponsored by the South African Institute for Aquatic Biodiversity (SAIAB). Numerous individuals from several academic and research institutions are thanked for their support and contributions to the bibliography. In particular, we are most grateful to the SAEO Elwandle Node staff for compiling the South African Estuarine Information System (http://www.saeonmarine.co.za/saeis) and making it available to all. The fact that references on the SAEIS database are freely available in pdf format has meant that some unpublished grey literature can now be included in this bibliography.

This report should be cited as follows:

An electronic copy of this report can be downloaded from the SANCOR website http://sancor.nrf.ac.za and a regularly updated version of the bibliography will available on the SAIAB website http://www.saiab.ac.za.
INTRODUCTION

In March 1993 a co-ordinated research programme on Decision Support for the Conservation and Management of Estuaries was launched under the auspices of the Consortium for Estuarine Research & Management (CERM) and funded by the Water Research Commission (WRC). A procedure was developed whereby decision support systems were to be structured around certain key issues, with currently available information and wisdom providing the basis for individual decision support modules. A collation of scientific information on individual southern African estuaries was identified as a high priority in order to facilitate subsequent components of the CERM contract with the WRC. To cater for this need, a separate WRC Report (No. 577/1/95) entitled *Available Scientific Information on Individual South African Estuarine Systems* was published in 1995.

In June 2000 it was recommended that an updated hard copy of the report be produced and this was implemented in July 2000 with the production of WRC Report No. 577/3/00. In addition to providing valuable data sources for individual systems, the more recent version also highlighted those estuaries for which limited information was available. The additional work and new interpretations concerning South African estuaries during the past decade has necessitated the production of this latest version which we hope will be of use to local and international estuarine scientists, students, environmental practitioners and managers. We have also used the bibliography to examine research outputs and trends in the South African estuarine science field.

APPROACH & ANALYSES

For the purposes of this report, estuarine systems have been divided into three major biogeographic regions, viz. subtropical from the Kosi Estuary in KwaZulu-Natal to the Mbhashe Estuary in the Eastern Cape, warm temperate from the Mendwana Estuary in the Eastern Cape to the Ratels Estuary near Cape Agulhas, and cool temperate from the Uilkraals Estuary to the Orange River mouth on the Northern Cape coast. Each estuary has been placed in one of the three biogeographic categories described above, a map of which is shown below.

![Map of southern Africa showing the three major biogeographic regions used in this document.](image)

Figure 1. Map of southern Africa showing the three major biogeographic regions used in this document.
Systems that do not function as estuaries using the widely accepted definition of Day (1980) were not included in this report and are listed in Table 1. Previously functional estuaries such as the Sout, Baakens, Ngqurha and Sipingo, which have been drastically altered as a result of canalization, industrialization and urbanization, are included in this report because of the potential for rehabilitation. The Papkuils, which may not have been a functional estuary in its natural state (and is now an industrial waste-water canal), is excluded from this analysis.

Table 1. Inlets to the sea (some of which are intermittent) that probably do not function as estuaries.

The following extremely small systems (Table 2) have catchments arising within the immediate coastal environment, are seldom linked to the sea, and make a minimal contribution (in some instances a zero contribution) to the overall estuarine biota of southern Africa. All these systems are excluded from this report because of their limited proven estuarine functions. However, this does not imply that they are unimportant ecosystems. There are also numerous small coastal stream inlets (micro-estuaries?) linked to the sea, especially along the Eastern Cape coast, which may or may not have estuarine attributes. These inlets, mostly unnamed, are included in Table 2 and require further study in order to determine whether they function as estuaries or not.
Table 2. Extremely small estuaries with very limited estuarine biota, as well as small coastal stream inlets whose functioning is currently unknown.

The estuarine classification system used in this review mainly follows that of Whitfield (1992), viz. permanently open estuaries, temporarily open/closed estuaries, estuarine lake systems, estuarine bays and river mouths. Langebaan has been added to the above estuary categories, a review of which is contained in Whitfield (2005a). That discussion came to the conclusion that the Langebaan system should be classified as an estuarine embayment and is therefore included in this analysis.

Individual systems may change from one estuarine type to another under the influence of natural events or anthropogenic influences. Human induced changes have resulted in rapid and dramatic alterations to a number of systems, e.g. Richards Bay has been transformed from an estuarine lake into two estuarine bays through harbour development. It should be noted that a water body must have a surface area exceeding 1000 ha to be considered as an estuarine lake or estuarine bay system. It should also be noted that permanently open estuaries and river mouths do sometimes close during prolonged drought periods, but that under normal seasonal river flow conditions they remain open. Increasing freshwater abstraction from perennial river systems for agricultural, domestic and industrial use will inevitably lead to changes in sediment scouring patterns and mouth dynamics, with concomitant changes in the future classification of these estuaries.

The condition of each estuary, which is based on the degree to which human activities have changed the functioning or viability of a particular system, is broadly classified as poor, fair, good or excellent. These assessments are based on the opinions of scientists from the different regions, use of Google Earth to view each estuary and its surrounding catchment, as well as information from the literature database presented in this report. The following criteria acted as guidelines in the designation of the condition of a particular estuary:

Excellent - estuary appears to be in a near pristine condition (negligible human impact).
Good - no major negative anthropogenic influences on either the estuary or catchment (low impact).
Fair - noticeable degree of ecological degradation in the catchment and/or estuary (moderate impact).
Poor - major ecological degradation arising from a combination of anthropogenic influences (high impact).
A biogeographical analysis of the current situation is given below (Table 3).

A subjective assessment of estuarine condition, based on expert opinion from the Whitfield (2000) bibliography, together with a more recent Google Earth view of catchment and estuary development/degradation was used to independently compare the state of each estuary to that obtained by van Niekerk & Turpie (2012) as part of the 2011 National Biodiversity Assessment (NBA) Report. Based on the 271 estuaries for which information was available, 179 had identical scores, 91 showed a single category difference, and one estuary differed by two categories. Table 3 represents the results from the 280 estuaries that were analysed and showed that a majority of systems (52%) were in a good or excellent condition, with 48% in a poor or fair condition. This table also revealed that the estuaries in the warm temperate biogeographic region were in the best condition when compared to those in the cool temperate and subtropical regions. Although 15 estuaries from the subtropical region were assessed as being in excellent condition, all these systems were located along the Pondoland coast and not in the highly developed KwaZulu-Natal region. This latter area had 24 estuaries (19%) in poor condition, which was more than the 9 estuaries in poor condition in the cool temperate zone but that latter figure equated to 35% of the 26 systems within that zone.
The estuary information categories are, of necessity, very broad and the contents of a number of papers cover more than one category. Although published works in scientific journals and books have received the most attention, numerous reports synthesizing both published and unpublished information on South African estuaries are also given. In addition, much of the ‘grey’ literature which is readily accessible has been included in this report but a number of documents were excluded on the basis that this type of information is not available to either scientists or managers (e.g. unpublished honours projects). Abstracts from conferences are also excluded from the database since these often cover preliminary findings which are published in detail at a later date.

Where an unpublished report or progress report duplicates information provided by the same author in a published article, the former document is excluded from this analysis. Likewise, if preliminary reports are followed by final reports which include the information given previously, then only the final document is indexed. Taxonomic papers dealing with the descriptions of species have not been included in this database. Selected references from both the marine and freshwater environment have been included where they contain considerable information directly relevant to estuaries or typical estuarine organisms. It is important to note that references listed in the section “General Estuarine References” are not repeated under the individual estuary headings. In a number of instances we have provided alternative isiXhosa and isiZulu spelling for the earlier accepted spelling and pronunciation of many estuaries in the Eastern Cape and KwaZulu-Natal.

Information availability on each estuary is categorized as nil, poor, moderate, good or excellent. Systems with 1-9 references were classified as poor, 10-19 as moderate, 20-39 as good, and 40+ as excellent. A preliminary analysis of the estuarine information database in the different biogeographic regions is shown in Table 4. Indications are that the status of information on 79% of South African estuaries was classified as nil or poor, with 10% having moderate information and 11% having good or excellent information. One third of the poor returns are from the former Transkei region of the Eastern Cape, where 82 out of 87 estuaries have little or no published information. A similar situation pertains to the former Ciskei, where 10 of the 14 estuaries have limited available information.

A long-term analysis of the number of references per decade over the past century revealed several interesting trends. From a low base in the 1950s and 1960s virtually all outputs went from strength to strength until the beginning of the 1990s, after which they went into decline (Figure 2). The reason for the decline in virtually all the analysed categories after 1991 appears to be directly related to the decline in highly productive researchers in the subsequent decades (Figure 3). Although the ‘brain drain’ and retirement factors may be partially responsible for the above decline, the exact reasons for this trend are unknown.

Overall, there appear to be similar outputs in terms of references from each of the major regions along the South African coast. This is particularly the case for physical and chemical studies (Figure 4). However, as far as biological and ecological studies are concerned, outputs are considerably higher in the Eastern Cape Province when compared to the Western and Northern Cape.
Figure 2. A decadal analysis of the number of references in different categories over the past century. The total number of publications in each decade is also shown.

Figure 3. Number of highly active researchers per decade as obtained from the first author of referenced publications, reports and thesis. To qualify as an active researcher in a particular decade, a minimum of five senior authored outputs had to be produced by that individual in the decade.

A total of 249 Masters and PhD theses on South African estuaries have been produced, with the overwhelming majority (173) covering biological and ecological topics (Figure 5). This was followed by the physico-chemical category with 51 theses, and environmental management and fisheries with 19 theses. Only six theses over the past century had a primary focus on socio-economic issues.
The graduation of Masters and Doctoral students in South African estuarine studies was dominated by four coastal universities (Figure 6), namely Nelson Mandela Metropolitan University (36%), University of KwaZulu-Natal (28%), Rhodes University (13%) and the University of Cape Town (12%). Together these universities accounted for 89% of all degrees awarded in the estuarine research field, with the remaining 12 universities responsible for 11% of graduates within this field. The reasons why the four coastal universities have dominated the supervision of postgraduate students is linked to the location of the universities, their infrastructure and funding resources, but perhaps most of all, the research interests of lecturing staff at these institutions. Certain staff at these universities have been responsible for training a large number of students during their careers and in many cases were succeeded by lecturers with similar interests to their own, thus continuing the tradition of...
estuarine research at that particular university. In other cases, collaboration within and between universities and research institutes created teams of researchers who worked together on estuarine programmes to the benefit of both the science and students at these institutions.

The presence of research institutes such as the Institute for Coastal Research at the University of Port Elizabeth, the South African Institute for Aquatic Biodiversity associated with Rhodes University, and the Oceanographic Research Institute associated with the University of KwaZulu-Natal, also contributed to the relative strengths of estuarine research at these universities, when compared to others where such collaborative links were absent. The importance of a university’s location in determining whether estuarine studies are a feature of these institutions or not can be gauged from the minimal student contribution to estuarine research by the large University of the Witwatersrand and Pretoria University. Conversely, the Walter Sisulu University is located relatively close to a large number of important estuaries in the Eastern Cape but has not fully utilized the training opportunities provided by these systems. The reasons for this mismatch can be traced back to the historically disadvantaged nature of this university and the pressures on graduating students to seek employment once a Bachelor’s degree has been obtained.

**Figure 6.** Diagram illustrating the graduation of Masters and Doctoral students in South African estuarine studies at various universities.

A temporal breakdown of the relative contributions by the different universities towards the production of Masters and Doctoral theses over time is shown in Figure 7. The important role of Nelson Mandela Metropolitan University in the training of postgraduate students in estuarine work from the 1970s to the present is most apparent. Similarly, Rhodes University and the University of KwaZulu-Natal have made important contributions over the same period, although the latter university seems to have faltered during the 1990s before increasing its outputs following the turn of the century. Again, these trends can be traced back to the changing staff composition in various departments at this university.

There appears to be a strong disjuncture between the peak in thesis production during the period 2002-2011(Figure 7) and the continued overall decline in published papers and reports in various disciplines during the same period (Figure 2). The reasons for this mismatch are obscure but may be related to a change in
emphasis by lecturers and scientists towards the training new Masters and Doctoral students, together with a reduced focus on the publication of results from these theses. This does, however, run counter to the pressures on supervisors to generate publications for their universities and institutes for subsidy and NRF rating purposes, although it is also true that government subsidies for postgraduate students graduating with these higher degrees has also increased markedly within the last decade. Another reason for the decline in published documents during the past two decades could be the curtailment of report outputs during this period. For example, a number of substantial Department of Environmental Affairs estuarine contracts with the CSIR came to an end during the 1980s and led to a major drop in outputs from this source during the 1990s and onwards (Figure 8).

MVOTI ESTUARY

LOCALITY: 29°24'03"S; 31°20'18"E
CLASSIFICATION: River mouth
CONDITION: Poor (Remarks: Supports a wide variety of birdlife despite severe organic pollution)
HEALTH (NBA ASSESSMENT): Green (Fair)

AVAILABLE LITERATURE
(a) PHYSICAL/Chemical: National Research Institute for Oceanology (1983c), Cooper (1993b), Cooper (1994a)

NONOTI ESTUARY

LOCALITY: 29°19'01"S; 31°24'29"E

REGION: Subtropical

CLASSIFICATION: Temporarily open/closed estuary

INFORMATION: Poor

CONDITION: Fair (Remarks: Encouraging signs of recovery from a severely polluted condition)

HEALTH (NBA ASSESSMENT): Blue (Good)

AVAILABLE LITERATURE

(a) PHYSICAL/CHEMICAL:

(b) BIOLOGICAL/ECOLOGICAL: Begg (1984a)

ZINKWASI ESTUARY

LOCALITY: 29°16'45"S; 31°26'35"E

REGION: Subtropical

CLASSIFICATION: Temporarily open/closed estuary

INFORMATION: Poor

CONDITION: Fair (Remarks: Organic pollution gives rise to periods of anoxia in the water column)

HEALTH (NBA ASSESSMENT): Green (Fair)

AVAILABLE LITERATURE

(a) PHYSICAL/CHEMICAL: National Research Institute for Oceanology (1981d)

(b) BIOLOGICAL/ECOLOGICAL: Begg (1984a)

SIYAYA ESTUARY

LOCALITY: 28°58'01"S; 31°45'44"E

REGION: Subtropical

CLASSIFICATION: Temporarily open/closed estuary

INFORMATION: Moderate

CONDITION: Fair (Remarks: Restoration of this estuary and its catchment is far advanced)

HEALTH (NBA ASSESSMENT): Brown (Poor)

AVAILABLE LITERATURE

(a) PHYSICAL/CHEMICAL:

(b) BIOLOGICAL/ECOLOGICAL: Mackay (1996), Schleyer & Roberts (1987)

MHLATHUZE ESTUARY

LOCALITY: 28°50'46"S; 32°02'56"E
REGION: Subtropical
CLASSIFICATION: Estuarine bay
INFORMATION: Good
CONDITION: Fair (Remarks: Previously part of the Richards Bay system)
HEALTH (NBA ASSESSMENT): Green (Fair)

AVAILABLE LITERATURE

(a) PHYSICAL/CHEMICAL: MacKay & Cyrus (2001a),
(d) REPORTS/DOCUMENTS: Connell et al. (1975a), Connell et al. (1976c), Cyrus et al. (2000), Hemens et al. (1975b), Hemens et al. (1975c), Institute of Natural Resources (1993e), McClurg et al. (1982), Venter (1972)

RICHARDS BAY ESTUARINE SYSTEM

LOCALITY: 28°48'40"S; 32°05'17"E
REGION: Subtropical
CLASSIFICATION: Estuarine bay
INFORMATION: Good
CONDITION: Poor (Remarks: Expansion of the harbour berths will lead to further loss of habitat)
HEALTH (NBA ASSESSMENT): Green (Fair)

AVAILABLE LITERATURE

(a) PHYSICAL/CHEMICAL: MacKay & Cyrus (2001a), van Tonder et al. (1986)

HLOBANE/NHLABANE ESTUARINE SYSTEM

LOCALITY: 28°39'39"S; 32°15'25"E
CLASSIFICATION: Estuarine lake system
REGION: Subtropical
INFORMATION: Moderate
CONDITION: Poor (Remarks: Restoration of the system possible by removal of the RBM barrage)
HEALTH (NBA ASSESSMENT): Brown (Poor)

AVAILABLE LITERATURE
(a) PHYSICAL/CHEMICAL:
(c) SYNTHESSES/REVIEWS: Begg (1978), Cyrus (2001)

ST LUCIA ESTUARINE SYSTEM

LOCALITY: 28°22'55"S; 32°25'32"E
REGION: Subtropical

CLASSIFICATION: Estuarine lake system
INFORMATION: Excellent

CONDITION: Fair (Remarks: But poor during drought conditions in absence of Mfolozi River connection)

HEALTH (NBA ASSESSMENT): Brown (Poor)

AVAILABLE LITERATURE

MGOBEZELENI ESTUARINE SYSTEM

LOCALITY: 27°32'10"S; 32°40'17"E
REGION: Subtropical

CLASSIFICATION: Estuarine lake system
INFORMATION: Poor

CONDITION: Good (Remarks: Estuary mouth area highly disturbed by human activities)

HEALTH (NBA ASSESSMENT): Blue (Good)

AVAILABLE LITERATURE
